# **TPK 4161 - VALUE CHAIN ANALYTICS**

Discrete event simulation  
Jørn Vatn/September 2020

# Motivation

- ▶ There are many systems for which it is not easy to do probabilistic assessment
  - ▶ Repair times, failure times, service times etc. are not exponentially distributed
  - ▶ Resources depend on spare parts, weather window and so on
  - ▶ Prioritization rules determine which component should be repaired first
  - ▶ etc.
- ▶ Stochastic simulation is one way to establish system performance
- ▶ Discrete event simulation is a sub-set of stochastic simulation which is very flexible from a modelling point of view

# What is Discrete-Event Simulation?

- ▶ In discrete-event simulation, the operation of a system is represented as a chronological sequence of events
- ▶ Each event occurs at an instant in time and marks a change of state in the system
  - ▶ For example, if the up- and down times of a system of components are simulated, an event could be “component 1” fails, and another event could be “component 2” is repaired
  - ▶ A third event could be that a customer arrives to a service desk
- ▶ Rather than explicitly assessing the performance of a system by the laws of probability, we just “simulate” the system, and calculate the relevant statistics to get the performance

# Components of a Discrete-Event Simulation engine

- ▶ **Clock:** The simulation must keep track of the current simulation time. Time advances in discrete jumps, that is, the clock skips to the next event start time as the simulation proceeds
- ▶ **Event:** A change in state of a system
- ▶ **PES** = pending event set: The simulation maintains a list of simulation events to happen in the future. The pending event set is typically organized as a priority queue, sorted by event time. That is, regardless of the order in which events are added to the event set, they are removed in strictly chronological order.

## Components of a DES, continued

- ▶ **Event notice:** An element in the PES describing when an event is to be executed. In our VBA the EventNotice(time,code,parameters) is used
- ▶ **Activity:** A pair of events, one initiating and the other completing an operation that transform the state of the entity. Time elapses in an activity. We usually assume that no continuous changes are taking place during the activity.
- ▶ **Random-Number Generator**
- ▶ **Statistics:** The simulation typically keeps track of the system's statistics
- ▶ **Ending Condition**

# Example

Consider a system with two components

- ▶ Failure times of component 1 in days: 8, 4, 10
- ▶ Failure times of component 2 in days: 7, 6, 4
- ▶ Repair times of component 1 in hours: 4, 6, 2
- ▶ Repair times of component 2 in hours: 26, 3, 6

# Visualization

- ▶ We may think of a “blackboard” as the container holding the pending event set
- ▶ We use “Post-It” sheets to hold the individual events
- ▶ The function `eventNotice()` is used to place one event to the blackboard, i.e.,
  - ▶ The timestamp for this event is given
  - ▶ An `onEvent()` function to call is given

# Visualization

- ▶ We may think of a “blackboard” as the container holding the pending event set
- ▶ We use “Post-It” sheets to hold the individual events
- ▶ The function `eventNotice()` is used to place one event to the blackboard, i.e.,
  - ▶ The timestamp for this event is given
  - ▶ An `onEvent()` function to call is given
- ▶ The function `getNextEvent()` is used to retrieve events from to the blackboard, i.e., the `onEvent()` function
- ▶ The events are retrieved in chronological order
- ▶ The clock is updated
- ▶ The `onEvent()` function is executed
- ▶ Required status variables are updated

# Required built-in functions

```
Function onFailure(compNo)
compNo.Status = Down
eventNotice clock + rndRepTime(), onRepair(compNo)
End Function
```

```
Function onRepair(compNo)
compNo.Status = Up
eventNotice clock + rndFailureTime(), onFailure(compNo)
End Function
```

System status:

Comp1 = Up

Comp2 = Up

System = Up

Clock = 0

Initially, and empty blackboard, i.e., no events in PES

$t = 8 \cdot 24 = 192$

onFailure(1)

System status:

Comp1 = Up

Comp2 = Up

System = Up

Clock = 0

Initializing, eventNotice: first failure component # 1

$t = 7 \cdot 24 = 168$

onFailure(2)

$t = 8 \cdot 24 = 192$

onFailure(1)

System status:

Comp1 = Up

Comp2 = Up

System = Up

Clock = 0

Initializing, eventNotice: first failure component # 2, inserted prior to failure of component # 2

$t = 7 \cdot 24 = 168$

onFailure(2)

$t = 8 \cdot 24 = 192$

onFailure(1)

System status:

Comp1 = Up

Comp2 = Up

System = Up

Clock = 0

Ready to go: getNextEvent -> onFailure(2)

NTNU

Norwegian University of  
Science and Technology

$t = 8 \cdot 24 = 192$

onFailure(1)

System status:

Comp1 = Up

Comp2 = Up -> Down

System = Up

Clock = 168

onFailure(2); (i) change status of component # 2

NTNU

Norwegian University of  
Science and Technology

$$t = 8 * 24 = 192$$

onFailure(1)

$$t = \text{Clock} + 26 = 194$$

onRepair(2)

System status:

Comp1 = Up

Comp2 = Down

System = Up

Clock = 168

onFailure(2); (ii) eventNotice for next repair of component # 2

$$t = 8 * 24 = 192$$

onFailure(1)

$$t = \text{Clock} + 26 = 194$$

onRepair(2)

System status:

Comp1 = Up

Comp2 = Down

System = Up

Clock = 168

getNextEvent -> onFailure(1)

NTNU

Norwegian University of  
Science and Technology

$t = \text{Clock} + 26 = 194$

onRepair(2)

System status:

Comp1 = Up -> Down

Comp2 = Down

System = Up -> Down

Clock = 192

onFailure(1); (i) change status of component #1

$t = \text{Clock} + 26 = 194$

onRepair(2)

$t = \text{Clock} + 4 = 196$

onRepair(1)

System status:

Comp1 = Down

Comp2 = Down

System = Down

Clock = 192

onFailure(1); (ii) eventNotice for next repair of component # 1

$t = \text{Clock} + 26 = 194$

onRepair(2)

$t = \text{Clock} + 4 = 196$

onRepair(1)

System status:

Comp1 = Down

Comp2 = Down

System = Down

Clock = 192

getNextEvent -> onRepair(2)

NTNU

Norwegian University of  
Science and Technology

$t = \text{Clock} + 4 = 196$

onRepair(1)

System status:

Comp1 = Down

Comp2 = Down -> Up

System = Down -> Up

Clock = 194

onRepair(2); (i) Change state of component #2 etc.

$t = \text{Clock} + 4 = 196$

onRepair(1)

System status:

Comp1 = Down

Comp2 = Up

System = Up

Clock = 194

... add new failure events, get next events and so on...

# Simulation Engine Logic

- ▶ Start of simulation
- ▶ Initialize Ending Condition to FALSE
- ▶ Initialize system state variables
- ▶ Initialize Clock
- ▶ Schedule one or more events in the PES

# Simulation Engine Logic

- ▶ Start of simulation
- ▶ Initialize Ending Condition to FALSE
- ▶ Initialize system state variables
- ▶ Initialize Clock
- ▶ Schedule one or more events in the PES
- ▶ While (Ending Condition is FALSE) then do the following:
  - ▶ Get the nextEvent from the PES
  - ▶ Set clock to nNextEvent time
  - ▶ Execute the nextEvent code and remove nextEvent from the PES
  - ▶ Update statistics

# Simulation Engine Logic

- ▶ Start of simulation
- ▶ Initialize Ending Condition to FALSE
- ▶ Initialize system state variables
- ▶ Initialize Clock
- ▶ Schedule one or more events in the PES
- ▶ While (Ending Condition is FALSE) then do the following:
  - ▶ Get the nextEvent from the PES
  - ▶ Set clock to nNextEvent time
  - ▶ Execute the nextEvent code and remove nextEvent from the PES
  - ▶ Update statistics
- ▶ Generate statistical report
- ▶ End of simulation

# Programming issues

- ▶ We will only consider the situation where we do the “programming” our selves
- ▶ An approach for VBA is presented
- ▶ We need some standard functions like `eventNotice()` and `getNextEvent()`
- ▶ If you write in C++, Python etc, you need to write those yourself, or find a library
- ▶ In all cases we need to write our own `onEvent()` functions

# Programming issues - Callback's

- ▶ In the `eventNotice()` we need to pass a function to be called when the event is retrieved from the PES
- ▶ Such a function we would like to pass is often denoted a `Callback`-function
- ▶ In programs like C++ we may pass the (memory) address' of the `Callback`-function, and when the event is retrieved the function at this address is used for the execution
- ▶ In standard VBA we cannot pass the address efficiently
- ▶ A workaround is to pass the function name of the `Callback`-function
- ▶ We should then use a dedicated `Select Case` construct for the execution

## CallbackLib-Simple

Below is an example of using the `callBack()`-function

```
Function Execute(onEvent As String)
Select Case onEvent
Case "onArrival"
    onArrival
Case "onServiceCompleted"
    onServiceCompleted
End Select
End Function
```

where `onEvent` is the name of the `callBack()`-function

## CallbackLib-Refined

- ▶ Often we need to pass parameters to the `callback()`-function. For example in the reliability example, we need to pass which component failed
- ▶ One way to accomplish this is to “wrap” both the name of the `callback()`-function and parameters
- ▶ Below we assume that we only need one parameter, and the “wrapping” is typically:
  - ▶ `onEventData = Array("onFailure", CompNo)`

## CallbackLib-Refined

```
Function Execute(onEventData As Variant)
Dim onEvent as String
Dim compNo as Integer
onEvent = onEventData(0)
compNo=onEventData(1)
Select Case onEvent
Case "onFailure"
    onFailure compNo
Case "onRepair"
    onRepair compNo
End Select
End Function
```

Note that we need to explicit state all `callBack()`-functions we are using

## Library functions in: DiscreteEventSimulation.xlsm

```
InitPES()  
eventID = eventNotice(time, onEventName, parameters)  
onEventData = getNextEvent()  
releaseEventNotice(eventID)  
Execute(onEventData)           ' Customization required !  
getClock()  
rndExponential(Mean)
```

# Example 1

- ▶ Customers are arriving to our service according to a Poisson process with parameter  $\lambda$
- ▶ The times between arrivals are then  $\sim \text{Exp}(\lambda)$
- ▶ We have one server that can treat the arriving customers
- ▶ The service rate is  $\mu$ , we assume exponentially distributed service times
- ▶ Objective: Find the mean number of customers in the system

▶ Solution in Excel VBA

## Example 2

- ▶ Consider a workshop with three critical machines
- ▶ Each machine has a constant failure rate equal to  $\lambda$  and there is one repair man that can repair failed machines
- ▶ The rate of repair is  $\mu$  meaning that the mean repair time is  $1/\mu$
- ▶ The system state variable represents the number of functioning machines

▶ Solution in Excel VBA

## Example 3

In this example we consider a system with one active and one passive (stand-by) pump

- ▶ The active pump has failure rate  $\lambda_A$ , where a failure will immediately be detected
- ▶ Mean time to repair for the active pump is MTTR
- ▶ The passive pump may fail in stand-by mode with a failure rate  $\lambda_P$ . Proof tests are carried out every  $\tau$  time unit. If the stand-by pump is successfully started upon a demand, we assume that it will not fail while the active pump is being repaired
- ▶ When the active pump is repaired, the stand-by pump goes back to a stand-by mode
- ▶ Repair time of stand-by pump = 0, but we cannot start the system before the active pump is repaired

▶ Solution in Excel VBA

## Example 4

In this example we consider on offshore wind turbine. If the turbine fails, we have to wait for the weather window to open

- ▶ The wind turbine has failure rate  $\lambda = 1/\text{MTTF}$ , where a failure will immediately be detected
- ▶ Mean repair time is MTTR
- ▶ Mean time for the weather window to open is gamma distributed, where the parameters depends on the season
- ▶ Winter season =  $8760/2$ , and summer season =  $8760/2$ , but we may change these...

▶ Solution in Excel VBA

## Example 5

In this example we consider a component with a *hidden function*

- ▶ The failure rate is  $\lambda$
- ▶ A proof test is carried out every  $\tau$  time unit to reveal hidden failures
- ▶ If the component is in a fault state at the test, a repair action is initiated
- ▶ Mean time to repair is  $1/\mu$

The objective is to find the probability that the system is in a fault state at a random point of time, i.e., the PFD = Probability of Failure on Demand

▶ Solution in Excel VBA

Thank you for your attention
